# ESSA RESEARCH LABORATORIES

The mission of the Research Laboratories is to study the oceans, inland waters, the lower and upper atmosphere, the space environment, and the earth, in search of the understanding needed to provide more useful services in improving man's prospects for survival as influenced by the physical environment. Laboratories contributing to these studies are:

**Earth Sciences Laboratories:** Geomagnetism, seismology, geodesy, and related earth sciences; earthquake processes, internal structure and accurate figure of the Earth, and distribution of the Earth's mass.

**Atlantic Oceanographic Laboratories and Pacific Oceanographic Laboratories:** Oceanography, with emphasis on ocean basins and borders, and oceanic processes; sea-air interactions; and land-sea interactions. (Miami, Florida)

**Atmospheric Physics and Chemistry Laboratory:** Cloud physics and precipitation; chemical composition and nucleating substances in the lower atmosphere; and laboratory and field experiments toward developing feasible methods of weather modification.

**Air Resources Laboratories:** Diffusion, transport, and dissipation of atmospheric contaminants; development of methods for prediction and control of atmospheric pollution. (Silver Spring, Maryland)

**Geophysical Fluid Dynamics Laboratory:** Dynamics and physics of geophysical fluid systems; development of a theoretical basis, through mathematical modeling and computer simulation, for the behavior and properties of the atmosphere and the oceans. (Princeton, New Jersey)

**National Hurricane Research Laboratory:** Hurricanes and other tropical weather phenomena by observational, analytical, and theoretical means; hurricane modification experiments to improve understanding of tropical storms and prediction of their movement and severity. (Miami, Florida)

**National Severe Storms Laboratory:** Tornadoes, squall lines, thunderstorms, and other severe local convective phenomena toward achieving improved methods of forecasting, detecting, and providing advance warnings. (Norman, Oklahoma)

**Space Disturbances Laboratory:** Nature, behavior, and mechanisms of space disturbances; development and use of techniques for continuous monitoring and early detection and reporting of important disturbances.

**Aeronomy Laboratory:** Theoretical, laboratory, rocket, and satellite studies of the physical and chemical processes controlling the ionosphere and exosphere of the earth and other planets.

**Wave Propagation Laboratory:** Development of new methods for remote sensing of the geophysical environment; special emphasis on propagation of sound waves, and electromagnetic waves at millimeter, infrared, and optical frequencies.

**Institute for Telecommunication Sciences:** Central federal agency for research and services in propagation of radio waves, radio properties of the earth and its atmosphere, nature of radio noise and interference, information transmission and antennas, and methods for the more effective use of the radio spectrum for telecommunications.

**Research Flight Facility:** Outfits and operates aircraft specially instrumented for research; and meets needs of ESSA and other groups for environmental measurements for aircraft. (Miami, Florida)

Tabulations of Propagation Data Over Irregular Terrain in the  
230- to 9200- MHz Frequency Range

Part II: Fritz Peak Receiver Site

by

P. L. McQuate, J. M. Harman, M. E. Johnson, and A. P. Barsis

This is the second part of a four-part report containing tabulations and graphs of transmission loss data resulting from propagation experiments in the 230- to 9200- MHz frequency range conducted over irregular terrain in Colorado. This part describes data obtained at a single common receiver site at Fritz Peak, Colorado, over propagation paths varying in length from 3.0 to 120 km.

1. Introduction

The purpose of this report series is to present transmission loss data resulting from propagation experiments over irregular terrain in Colorado, with path lengths ranging from 0.5 to 120 km at seven frequencies in the 230- to 9200- MHz range. This measurement program was sponsored by the U. S. Army Electronics Command and by the U. S. Army Security Agency as part of a study of propagation characteristics and communication systems performance under conditions similar to those encountered by an army in the field.

Descriptions of the equipment used, of measurement procedures, and of initial data presentation and analysis are contained in Part I of this report (McQuate et al., 1968). The presentation of the data in Part II differs from that in Part I only in the following:

1. No individual photographs of the transmission path from the common receiver site toward the transmitter location were obtained. The panoramic photographs, figures 2 and 3, provide an indication of the foreground in the various directions and include bearing indications for comparison with the detailed path data in the subsequent sections.
2. The principal results, consisting of graphs of basic transmission loss versus receiving antenna height for each frequency, were obtained directly from computer outputs with the use of a microfilm plotter. Computer operations and additional data analysis, which will be reported on separately, were supported by the U. S. Air Force Space and Missile System Organization (SAMSO).

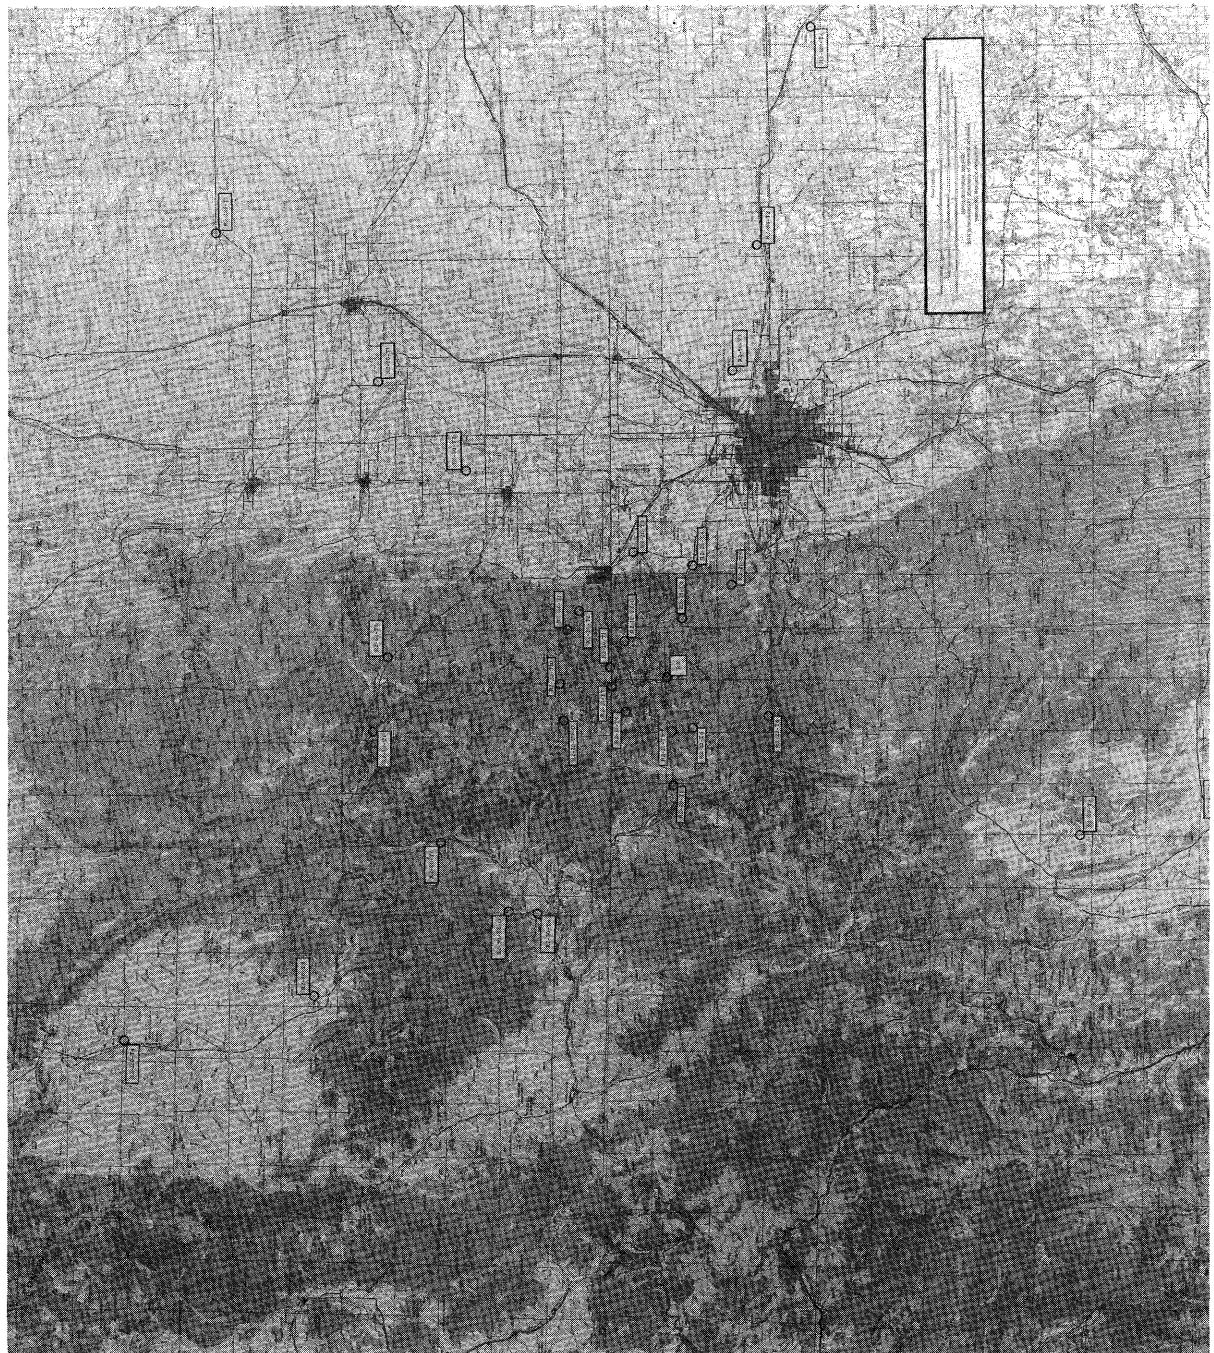

3. Part I of the report contained a number of comparisons of basic transmission loss values obtained over the same paths on different dates. Since only very few paths pertaining to the R-2 site were rerun, the comparison graphs are omitted here.

The Fritz Peak receiver site (designated R-2) shown in figure 5, is located in the mountainous terrain west of Boulder at the foot of Fritz Peak, which shields the site from the eastern plains, about 20 km

distant. Consequently, the majority of the transmitter sites (36 of 44) associated with this receiver site are located in the mountains, and the data represent propagation conditions in extremely rough terrain to the northwest. An estimated 90 percent of the foliage in this test area is coniferous. Figure 1 is a map of the area, showing the common receiver site R-2 and most of the transmitting locations, which were arranged in concentric circles around it. A large building approximately 50 m from the receiving antenna, as seen in figures 2 and 3, prevented the establishment of transmitting sites in the sector from  $125^{\circ}$  to  $160^{\circ}$  measured east of true north. Figure 2 is a panoramic view of the immediate foreground taken from the top of the 13 m tower, and figure 3 is the same panoramic view taken from a height of approximately 1 m above ground.

As already noted, further details regarding measurement techniques, equipment, and data presentation can be found in Part I of this report (McQuate et al., 1968).

## 2. Acknowledgements

Nearly all personnel within the Spectrum Utilization Task Area of the Tropospheric Telecommunication Laboratory participated in the collection, analysis, and evaluation of the data.

## 3. Reference

McQuate, P. L., J. M. Harman, and A. P. Barsis (1968), "Tabulations of propagation data over irregular terrain in the 230- to 9200-MHz frequency range, Part I: Gunbarrel Hill receiver site," ESSA Tech. Rept. ERL 65 - ITS 58.

## 4. Data Tabulations

Propagation data tabulations are presented on pages 9 through 158. Meteorological data obtained during daylight hours concurrently with the transmission loss measurements at each site are tabulated on pages 159 through 171.

In addition, USGS quadrangle information, helpful in checking terrain profiles, is provided on pages 172 through 185. For each path, intercepts of the great-circle path with the edges of the listed quadrangles are given, together with the distance from the common receiver site

The path near the transmitter crosses a dirt road and then follows a narrow mountain valley for 800 m. The horizon is formed by ridges 1800 m away, covered with coniferous trees. Power and telephone lines parallel both sides of the dirt road, which runs at  $20^{\circ}$  to the path.

The transmitter is located on a mound of waste material from a mine approximately 10 m above the surrounding terrain. A few trees and brush grow about 100 m away. A metal building is to the left of the path and 46 m from the antennas. No power or telephone lines are in the area. Dense pines fill the area to the left of the path 180 m away.

The immediate foreground drops quickly away from the transmitter. The terrain is covered with scrub pine and field grass for 60 m to a small stream. Beyond the stream the path extends over rolling hills covered with pines. A deserted cabin sits just to the right of the path, about 350 m away. No other obstructions exist.

The immediate foreground is open plains covered with grass. An asphalt highway crosses the path approximately 200 m from the transmitter. A 4-wire power line parallels the highway which, after crossing the path at  $40^\circ$ , turns and parallels the right edge of the path. About 1.5 km away, steeply sloping hills form the horizon.

This site is located on a pile of mining waste material. Fifteen meters from the transmitter, the grass-covered ground drops sharply. Twenty meters away stands a dense grove of aspen trees, below the line of sight. About 100 m away the ground slopes gently upward to a pine-covered ridge, which forms the horizon 1.5 km away.
